2. Projectomschrijving

2.1 Samenvatting

The "Smooth Bite for All" project focused on oral mechanisms involved in sensory perception and food intake regulation in relation to food structure. Factors which contribute to dynamic sensory perception and food intake regulation were established by determining relationships between food properties, oral behaviour and consumer characteristics. The SBfA project contributed to a more comprehensive understanding of how transformations of structural heterogeneities during oral processing provide signals for sensory perception and liking; and how a variety of food structure and texture modifications can be used to steer oral processing behaviour and regulate food intake. The SBfA project demonstrated how oral behaviour can determine bolus properties and consequently explain inter-individual differences in dynamic sensory perception consumers. The SBfA project demonstrated how desired texture and taste sensations can be enhanced by modifications of the food structure (texture contrast). The fundamental knowledge generated by the project helped food industry to develop healthier products. The SBfA project provided guidelines for food industry to stratify and customize product formulations.

2.2 Doel van het project

The aim of the project was to determine the influence of structural and textural food properties and expectations of foods on bolus properties, oral processing behaviour, dynamic sensory perception and liking in consumer groups varying in age, ethnicity and eating capability.

2.3 Motivatie

Increasing concerns regarding overweight and obesity require a better understanding of factors contributing to energy intake. It is of great interest to quantify the extent to which the modulation of food properties such as its texture can be used to steer oral processing behaviour in order to

regulate the amount and energy of food consumed. The SBfA project developed relationships between rheological, mechanical, tribological and texture properties of foods and energy intake.

2.4 Resultaat

The SBfA project demonstrated that oral processing behaviour of a broad range of foods and beverages depends on both food properties and consumer characteristics. The SBfA project described how oral processing behaviour of drinkable, spoonable and chewable foods is determined by rheological and mechanical properties, rather than liking of and familiarity with the foods. We determined inter-individual variability in eating behaviour in consumer groups differing in age, gender and ethnicity. The SBfA project revealed consistent differences in eating rate of a broad range of foods and beverages between males and females, between adults and elderly as well as between Chinese and Dutch consumers. The SBfA project observed that oral physiological characteristics of consumers explain inter-individual variations in oral processing behaviour only to a very limited extend and suggested that other physiological and cultural factors might explain the inter-individual variations better. This knowledge can be used to contribute to the development of customized foods targeted towards specific consumer groups.

The SBfA project demonstrated how food structure and texture modifications can be used to influence eating behaviour and regulate food intake. Structure and texture manipulations cause considerable changes in dynamic sensory perception and can be applied to regulate energy intake. The SBfA project showed how addition of particles such as fruit, granola or vegetable pieces to food matrices such as yogurts, soups and processed cheeses affects eating behaviour and eating rate. The SBfA project revealed which specific properties of the added particles (Young's modulus, fracture stress and strain, particle size and number) steer oral processing behaviour. Eating rate of semi-solid foods can be slowed down by addition of particles by up to 60% while increasing liking. The SBfA project showed that more subtle, smaller modifications of food texture, for example size of granola particles added to yogurt, can be sufficient to influence oral processing behaviour and consequently regulate food and energy intake. The SBfA project demonstrated that the addition of particles to food matrices with undesirable texture properties can be used to shift consumers perception towards desirable sensations. The SBfA project suggested that this approach can be used as a novel strategy to compensate for undesired texture perception in, for example, high-protein foods.

Many foods that are consumed on a daily basis are combinations of food items with very different properties, so called composite foods. Examples of composite foods include combinations of toppings such as cheeses with breads or combinations of condiments such as mayonnaises with French fries or salads. Little is known about how the properties of condiments and toppings influence oral behaviour, sensory perception and food intake of composite foods. The SBfA project demonstrated that for composite foods texture perception is driven by the solid carrier whereas flavour perception is driven by the condiments. The SBfA project showed that the sensitivity to discriminate between condiments differing in fat level and viscosity decreases considerably when they are consumed together with carrier foods which has major implications for the development of reformulated, low fat condiments by food industry. The SBfA project showed that addition of condiments to carrier foods assists saliva in the formation of a safe-to-swallow bolus which increases eating rate and can consequently be used to increase vegetable and energy intake in vulnerable populations such as the elderly. The SBfA project demonstrated how the shape and size into which vegetables are cut during food preparation controls eating rate of vegetables and could potentially be used to increase vegetable intake in children and adults. By those means the project revealed several ways how food structure and texture can be modified to influence eating behaviour and regulate food intake.

Regarding food structure modifications at smaller length scales to optimize sensory perception, the project demonstrated how oil droplets in liquid o/w emulsions and semi-solid emulsion-filled gels can

be clustered to modify rheological, mechanical, tribological and sensory properties of foods. The SBfA project developed new methodologies to cluster oil droplets in model o/w emulsions and model emulsion filled gels, so that aqueous phase is entrapped within the oil droplet cluster which increases the effective volume fraction of the oil phase and alters rheological and tribological properties by up to three order of magnitude. The SBfA project showed that the clustering of oil droplets in o/w emulsions and emulsion-filled food gels can be controlled using a variety of methodologies (charge based hetero-aggregation, protein-polyphenol interactions). The SBfA project demonstrated that the length scale of the oil droplet clusters and the interaction strength between oil droplets in a cluster determine sensory perception. The SBfA project suggests that clustering of oil droplets might be used to enhance perception of fat-related sensory attributes and might therefore potentially be a novel tool to reduce fat content in foods without affecting sensory perception.

Furthermore, the SBfA project investigated conceptual ideas and processes underlying dynamic sensory perception, hedonic perceptions and food-evoked emotions of consumers. The SBfA project investigated how consumers conceptualize dominance of sensations using TDS by comparing sensory profiles obtained with different definitions for dominance. The SBfA project demonstrated that different task instructions given to the consumer resulted in similar sensory profiles or as you put it "Instructions do not matter much". The SBfA project modified the TDS methodology by introducing a Hold-down procedure where consumers actively hold down an attribute button to describe their dominant sensation, and release the button when they no longer perceive the attribute as dominant. This 'hold-down' procedure allows to quantify implicit indecisive behaviour in attribute selection. However, no dominance durations between attribute selections were too short to reflect periods of true hesitation of consumers. In sensory evaluations, consumer taste and evaluate usually single bites of foods. Since this does not necessarily reflect perception during normal food consumption, the SBfA project explored perception and liking of foods consumed with multiple bites. The SBfA project demonstrated convincingly that some sensations built-up from first to last bite suggesting that multiple bite sensory evaluations provide additional information about products which cannot be captured by standard single bite evaluations. These findings could be generalized to a broader range of products ranging from cheeses, breads, drink yogurts to vegetarian sausages. Sensory perceptions changed from first to last bite for all products further strengthening the evidence that multiple bite assessments provide additional information about a consumer's food experience beyond first bite perception. The SBfA project demonstrated that the decline of desired and built-up of undesired sensory perceptions from first to last bite contributed to the decline in product liking during consumption. Food-evoked emotions have been suggested to add to the understanding of food choice. The SBfA project compared implicit and explicit measures of food evoked emotions during multiple bite food consumption. The SBfA project observed that the food evoked emotions determined implicitly by facial expressions and explicitly by TDE showed little overlap and were not directly comparable. Only limited changes in food-evoked emotions were observed from first to last bite. The SBfA project showed that food-evoked emotions directly reflect liking and did not provide additional information beyond liking.

The SBfA project published over 30 papers in scientific, peer-reviewed journals. Over 90% of the publications of the SBfA are published in Q1 journals. Some of the publications of the SBfA journal belong to the top 1% and top 10% of the most cited publications in the field. All six PhD projects of the SBfA project were completed and successfully defended in-time. Five out of six PhD's started to work for food industry or in academia shortly after completion of the PhD thesis. All team members of the SBfA project including its industrial partners Groupe Bel, Unilever and FrieslandCampina meet three times per year. In addition, the project team visited each company once per year on their location to ensure knowledge transfer.

4. Behaalde resultaten

4.1 Korte beschrijving van de inhoudelijke resultaten

The "Smooth Bite for All" project focused on oral mechanisms involved in sensory perception and food intake regulation in relation to food structure. Factors which contribute to dynamic sensory perception and food intake regulation were established by determining relationships between food properties, oral behaviour and consumer characteristics. The SBfA project contributed to a more comprehensive understanding of how transformations of structural heterogeneities during oral processing provide signals for sensory perception and liking; and how a variety of food structure and texture modifications can be used to steer oral processing behaviour and regulate food intake. The SBfA project demonstrated how oral behaviour can determine bolus properties and consequently explain inter-individual differences in dynamic sensory perception consumers. The SBfA project demonstrated how desired texture and taste sensations can be enhanced by modifications of the food structure (texture contrast). The fundamental knowledge generated by the project helped food industry to develop healthier products. The SBfA project provided guidelines for food industry to stratify and customize product formulations.

4.2 Deliverables

- Scientific knowledge on interrelationships between food structures, structural heterogeneities, bolus properties, food oral processing, expectations, sensory and emotion perception and liking in different consumer groups
- Understanding of interactions between temporal sensory, emotional and hedonic perceptions
- Guidelines for food industry to efficiently and selectively stratify and customize product formulations
- Over 30 publications in scientific, peer reviewed journals
- 6 PhD theses
- Expert discussion meetings: All team members meet with the industrial partners of the project (Groupe Bel, Unilever and FrieslandCampina) three times per year (12 times in total)
- SBfA project team visited each company around once per year at their R&D centre.

8 Impact

Beschrijf de impact van het project

The "Smooth Bite for All" project contributed to a more comprehensive understanding of how transformations of structural heterogeneities during oral processing provide signals for sensory perception and liking; and how a variety of food structure and texture modifications can be used to steer oral processing behaviour and regulate food intake. The SBfA project demonstrated how oral behaviour can determine bolus properties and consequently explain inter-individual differences in dynamic sensory perception consumers. The SBfA project demonstrated how desired texture and taste sensations can be enhanced by modifications of the food structure (texture contrast). The fundamental knowledge generated by the project helped food industry to develop healthier products. The SBfA project provided guidelines for food industry to stratify and customize product formulations targeted towards the needs of consumers. The guidelines provided by the SBfA project contributed to the research and product development activities of Groupe Bel, Unilever and FrieslandCampina. The SBfA project performed fundamental scientific research (TRL 1-3) and delivered over 30 publications in excellent journals. The project considerably strengthened the networks of all partners involved.
